Malware Landscape 2022
A Study of the Scope and Distribution of Malware

Executive Summary

Malware — malicious code that can infect and compromise any device connected to a network, including computers, smartphones, “smart home” devices, and industrial control systems — is a rapidly growing security threat. Malware can interfere with the operation of computer systems and networks; delete, suppress, or block access to data; and otherwise re-direct computing resources from legitimate to criminal purposes.

Some types of malware create criminal hosting infrastructures ("botnets") that can be used to perpetrate spam or phishing campaigns, or to disrupt services or merchant activities through denial-of-service attacks. Criminals use a wide variety of endpoint malware that serve different purposes, e.g., information stealing malware such as banking trojans for identity theft or financial fraud, or backdoor trojans for remote control execution or administration. A particularly vicious type of malware ("ransomware") is an effective agent of digital extortion.

Malware has become an organized criminal business. Like legitimate businesses, malware also depends on the services of the global Internet. The purpose of this report is to quantify how malware perpetrators use Internet resources for nefarious purposes.

For this study we captured nearly 5 million malware reports from four widely respected threat intelligence sources: Malware Patrol, MalwareURL, Spamhaus, and URLhaus. Analyzing these reports yielded important insights into what malware was most prevalent, where malware was served from or distributed, and what resources criminals used to pursue their attacks.
Principal Findings

Malware reports growing

299k reports in April 2021
800k reports in March 2022

Asia-Pacific networks host most IoT malware

China, India, and Australia host 81% of malware that targeted IoT devices

Malware attackers use fewer domains but to great effect

65% use IP addresses, 35% use domains

North America Nexus

8 of top 10 gTLD registrars of malware domains are headquartered in North America
US-based networks host most Endpoint Malware

Attackers target portals, file sharing and storage services, and code repositories

To distribute source code, attack code, and supplementary files

Cooperative efforts can mitigate malware

Service providers, law enforcement, and governments must work together to mitigate malware threats
Future Opportunities
Mitigating malware requires cooperation and determined efforts by all parties that comprise the naming, addressing, and hosting ecosystem exploited by cyberattackers:

- Hosting or cloud service providers are in the best position to scan their IP address delegations for malware and to remove malware if detected or reported by investigators.
- Registrars and registries are positioned to identify and suspend domains reported for serving malware.
- Hosting services, cloud services, registrars, and registries should have terms of service that allow them to suspend domains for malicious and illegal activity and should make concerted efforts to enforce them.
- Legislation or regulation may be necessary to effectively mitigate malware threats.
